Abstract

Using agricultural professionals’ forecasts of future farmland values and corn and soybean cash prices for their service area, we analyze whether their land and corresponding crop price expectations are consistent. We find that changes in expected land prices over time are positively correlated with expected crop price changes, suggesting these two forecasts are somewhat consistent. More importantly, we find that the linkage between these two forecasts is significantly stronger in the medium- and long-term as opposed to the short-term, as well as a substantially stronger correlation for districts that have heavier reliance on crop production as a net farm income source.

Acknowledgement

This work was supported in part by the USDA National Institute of Food and Agriculture Hatch projects 1010309, and NC1014, NC221, NCT-194.

49 Expert opinion surveys are commonly used to forecast future events, such as political election
50 results or critical future market outcomes such as oil and gas prices, inflation and interest rates,
51 economic growth, and key commodity market fluctuations. With respect to agricultural markets,
52 agricultural commodity futures and options markets are typically used to gauge critical
53 movements in key markets like corn or soybeans. On the other hand, there are few surveys that
54 consistently and systematically solicit opinions of agricultural professionals or producers
55 regarding future farmland price changes.¹ One prominent example is the survey of farm
56 managers and rural appraisers at the annual Soil Management and Land Valuation (SMLV)
57 conference organized by Iowa State University. In many of these opinion surveys, respondents
58 are expected to forecast both future land and crop prices (Federal Reserve Bank of Chicago
59 2017; Purdue University and the CME Group 2017). However, as far as we know, the previous
60 literature hasn't closely examined the relationship between respondents' land and crop price
61 forecasts in these expert or producer opinion surveys.

62 Using individual responses from 162 agricultural professionals that attended the May, 2016
63 SMLV conference, we examine the consistency between agricultural professionals' land price
64 forecasts with their corresponding corn and soybean price forecasts. We examine the consistency
65 of these price forecasts in three dimensions: first, we examine the temporal consistency of price
66 forecast within an individual market—corn, soybean, or land—over time. Second, using
67 correlation statistics, we explore whether agricultural professionals' price forecasts are consistent
68 across agricultural commodity markets, and more importantly, whether they are consistent across
69 crop and land markets. Third, we examine how the relationships between these expectations vary
70 across the forecasting horizon (short- vs. medium-to-long-term) and reliance on crop income.

71 **Data**

72 Sponsored by Iowa State University College of Agriculture and Life Sciences and Iowa State
73 University Extension and Outreach, the SMLV conference is regularly attended by farm
74 managers, rural appraisers, real estate brokers, and others interested in the land market in Iowa
75 and across the Midwest. This is the longest running conference at Iowa State—its ninetieth
76 meeting was held in 2017. The SMLV conference has consistently received strong support from
77 the Iowa Chapter of American Society of Farm Managers and Rural Appraisers throughout the
78 years. Every year, the Iowa Appraiser Examining Board and Iowa Real Estate Commission
79 approve the conference for six hours of continuing education credits for renewal of real estate,
80 appraiser, and broker licenses. At the conference, participants get an update on various current
81 issues in farm management, rural property appraisal, and the agricultural sector in general. In
82 addition, since 1964, every participant has an opportunity to “gaze into their crystal ball” and
83 provide their estimates of future corn and soybean prices and land values in Iowa.

84 Figure 1 shows the half-page sheet presented to conference participants on site asking about their
85 estimates of future land values, as well as corn and soybean prices. At the May 2016 conference,
86 186 out of 280 conference participants completed and returned their estimates, providing our
87 study sample. We further deleted 24 observations with missing values on either land or crop
88 forecasts. The final data consist of 162 observations.

89 We solicited participants’ opinion-based farmland price forecasts for five horizons, which is a
90 mix of short-, medium-, and long-term forecasts. The short-term forecast estimates land prices
91 six months after the conference (November 2016). The medium-term forecasts explore land
92 values in the two-to-five-year range (November 2017 and November 2020). The long-term
93 projections look 10 to 25 years out. In addition to land value questions, participants are also

94 asked to predict corn and soybean cash prices for their service area in November 2016, 2017, and
95 2020.

96 In this article, we are interested in the consistency of land and corn price forecasts from the
97 SMLV conference. We are particularly interested in whether the land price implied in a
98 respondent's crop price forecast is consistent with the self-reported land price forecast for the
99 same horizon. As a result, we mainly rely on the short- and medium-term land and crop price
100 forecast questions in this article. We drop the long-term forecast questions for 2025 and 2040 as
101 there are no corresponding forecasted commodity prices.

102 **Results – Graphical Analysis**

103 **I. Time Consistency of Expectations**

104 Table 1 summarizes the data and Table 2 presents the correlation statistics between short-term
105 (six-month) expectations with medium-term (18-month and 54-month) expectations for both
106 crop and land prices. The three graphs shown in Figure 2 further provide graphical evidence of
107 consistency of price forecasts over time for corn, soybean, and land prices. They clearly reveal a
108 strong (greater than 0.8) correlation between agricultural professionals' short-term, six-month
109 expectation with their medium-term, 18-month price expectation in each of the markets. This
110 suggests that agricultural professionals who hold a more optimistic view of near-term crop or
111 land market values within six months tend to project higher 18-month corn prices than their
112 peers—the corn price forecasts for 2016 and 2017 are mostly clustered between \$3.00/bushel and
113 \$4.00/bushel, or more specifically between \$3.50/bushel to \$4.00/bushel, with a few pessimistic
114 agricultural professionals projecting a \$2.00/bushel corn price. Similarly, those who reported
115 much higher soybean or land price forecasts for 2016 compared to others tend to forecast higher
116 prices for these markets for 2017 or 2020 as well.

117 As of May 2016, the price estimate for November 2016 seems to be less correlated with that of
118 November 2020, when compared to the correlation between the November 2017 and November
119 2020 price expectations, suggesting that most agricultural professionals forecast a turnaround in
120 the crop and land markets in late 2017 and a transition from dwindling crop and land prices to a
121 slow rebound.

122 **II. Cross-Market Consistency of Expectations**

123 *Cross-market correlation in forecasted prices*

124 Next, we examine whether the reported price forecasts are consistent across different agricultural
125 commodity groups, and more importantly, whether the commodity price forecast is consistent with
126 land price forecast. First, Figure 3 shows the correlation between the corn and soybean price
127 forecasts for both November 2016 and November 2020. The strong correlation between corn and
128 soybean price forecasts for both 2016 and 2017 clearly shows that the participating agricultural
129 professionals realize the interconnectedness across agricultural commodity markets and have a
130 similar view regarding the future trends for corn and soybean prices. It is also interesting to see
131 that the crop price forecasts for 2020 are more dispersed compared to those for 2016, suggesting
132 heterogeneous expectations regarding the future corn-to-soybean price ratios, which has
133 significant implication of crop rotation choices.

134 We further compare the reported corn price forecast by a respondent with their reported land
135 price forecast for 2016 and 2020. Figure 4 shows a scatterplot of respondents' corn price
136 forecasts with same-year land price forecasts. A visual examination of Figure 4 seems to suggest
137 that there is no obvious correlation or clear trend between the corn price and land price forecasts.
138 The lack of correlation is true for both 2016 and 2020 values. As discussed earlier, it seems that
139 the participating agricultural professionals' corn price forecasts are more clustered between

140 \$3.00/bushel and \$4.00/bushel, however, their land price forecasts have a much larger
141 variability, ranging from \$4,000/acre to \$10,000/acre.

142 Table 3 presents cross-market correlation statistics between the corn and soybean markets, as
143 well as crop and land market price expectations. This table shows a similar pattern as in Figures
144 3 and 4 but it also investigates the correlation between soybean price forecasts and land price
145 forecasts. While the correlations remain very consistent among the crop price projections over
146 the various time periods, the correlations between the crop price and land value projections
147 evolves over time with the higher correlations being observed as the time gap between the crop
148 price and land value projection period grows.

149 It seems rational to suggest that agricultural professionals seem to rely on corn (soybean) futures
150 prices when reporting corn (soybean) price forecasts, and thus report a fairly similar value. In
151 contrast, these participants may rely more on the recent farmland transactions or appraisals in
152 their local service areas as a reference for the future farmland market. As shown in Figure 1, we
153 ask participants to forecast land prices for their service area (i.e., the area in which they provide
154 professional service), which helps explain the wide range in their responses for the forecasted
155 land prices. In other words, the agricultural professionals may rely on different information when
156 forecasting crop and land prices—the crop futures market could easily be used as a benchmark
157 when forecasting crop prices, however, land price is driven by a host of other characteristics
158 beyond crop prices, including, most notably, land quality, crop yields, and crop-livestock mix, as
159 well as local market characteristics like proximity to urban areas.

160 *Cross-market correlation in forecasted price changes*

161 Differences in information sources and systems resulted in the seemingly apparent lack of
162 correlation between forecasted crop prices and land prices. However, because the comparison in
163 Table 3 is for price levels rather than changes in forecasted prices over time, this does not
164 necessarily mean that they are inconsistent, as agricultural professionals' expected land market
165 fluctuations may still be correlated with expected crop market fluctuations. As the results in
166 Table 3 showed, the correlation structure strengthens as the time gap between the forecast
167 periods grows.

168 We examine whether there is a positive relationship between changes in their corn price forecasts
169 from 2016 to 2017 or from 2016 to 2020 and changes in land prices for the same time period.
170 With USDA and the Federal Reserve frequently reporting changes in farm income and asset
171 values, it is possible that agricultural professionals are forecasting future market trends in
172 percentage change terms. Figure 5 shows two scatterplots and the fitted linear regression line
173 connecting percentage change in a respondent's corn price forecast from 2016 to 2017 with the
174 percentage change in their land price forecast. It shows that there is a positive relationship
175 between corn price changes and land price changes from 2016 to 2017.

176 *Short-term vs. Long-term correlation*

177 Economic theory of land value argues that the farmland market represents the net present value
178 of all future income streams, and farmland is often treated as a long-term investment. As a result,
179 land price changes are not only linked with contemporaneous crop market fluctuations, but also
180 reflect future crop market changes, in addition to other factors such as interest rates, land quality,
181 urban influences, etc. As a result, we perceive a stronger correlation between crop price outlook
182 with land price outlook in the longer term than that in the short-term, especially given that

183 agricultural professionals seem to benchmark their crop price forecasts to prices from the futures
184 markets.

185 The upper part of Figure 5 focuses on the short-term expectation changes from 2016 to 2017,
186 while the lower part shows the medium-to-long-term expectation changes from 2016 to 2020.
187 This reveals that there is a positive relationship between corn price changes and land price
188 change, and the positive correlation is stronger for the medium-term expectation changes than for
189 the short-term. The fitted line suggests that a one-percent increase in expected corn price from
190 2016 to 2017 would lead to about a corresponding 0.2 percent expected rise in land value, while
191 a one-percent increase in expected corn price from 2016 to 2020 would lead to a corresponding
192 0.4 percent increase in expected land value. The higher magnitude suggests that the short-term
193 land value expectations by agricultural professionals could be influenced by a host of factors
194 other than crop price fluctuations, however, their medium-to-long-term land value expectations
195 are more aligned with fluctuations in underlying assets such as corn.

196 Table 4 offers additional insights on the pairwise correlation statistics between the percentage
197 changes in expected crop prices with percentage change in expected land prices by analyzing the
198 linkage between soybean price expectations with land price expectations. Interestingly, the
199 correlation between soybean price changes with land price expectations for both short-term and
200 medium-to-long-term is statistically higher than that between corn and land price expectations,
201 this suggests agricultural professionals seem to place a higher weight on fluctuations in the
202 soybean market than the corn market when forecasting future farmland prices. This could be a
203 result of growing significance of soybean in the crop mix in Iowa and across the Midwest over
204 the past century, especially over the last fifty years (USDA NASS 2017c).

205 *Correlation for crop-intensive vs. non-crop-intensive regions*

206 The final aspect of the cross-market correlation we examine is the difference resulting from the
207 variation in crop-livestock mix and thus the varying degree of reliance on crop income. The
208 capitalization model suggests that localized land market tends to result from localized farm
209 income trends, and thus we argue that for regions that rely more heavily on crop production and
210 crop income, the crop market movements would be more significantly capitalized and
211 correspondingly we could expect to see a greater correlation in agricultural professionals' crop
212 price predictions with land price predictions for these crop-intensive regions. In light of this, we
213 broke the nine crop reporting districts in Iowa into two distinct groups—crop-intensive districts
214 in which crop production and crop income plays a relatively larger role in driving net income,
215 including Northwest, North Central, West Central, and Central Iowa; and non-crop-intensive
216 districts in which crop income plays a relatively smaller role and other sources of income, such
217 as livestock income or pasture production, can provide more influence. Although this is a
218 distinction between areas in Iowa, the logic that greater correlation between crop and land
219 market movements for crop-intensive areas applies well beyond the state.

220 Table 5 replicates the correlation statistics shown in Table 4, but rather than pooling all
221 observations, we separately correlate expected land price change with expected corn price
222 change for crop-intensive districts and non-crop-intensive districts. We reconfirm our findings
223 earlier that there is a stronger link between expected crop price changes with expected land price
224 changes in the medium-to-long-term as opposed to short-term, regardless of crop intensity. More
225 interestingly, our results reveal a much stronger correlation between crop market movements and
226 land market fluctuations. In crop-intensive districts, a one-percent increase in expected corn
227 prices from November 2016 to November 2017 would lead to a 0.25 percent increase in the

228 corresponding expected land prices, which is substantially higher than the average marginal
229 effect for the non-crop-intensive districts.

230 **Conclusions and Practical Implications**

231 Using agricultural professionals forecasts of short- and medium-term farmland values and crop
232 prices in the future for their service area at Iowa State University's SMLV conference, we
233 provide the first formal examination whether and how their land and corresponding corn and
234 soybean price expectations are consistent. Our results demonstrate that a positive correlation
235 between expected crop price changes and expected land price changes, suggesting that these two
236 forecasts are consistent. More importantly, we find that while the correlation between the six-
237 month, short-term land and crop price forecasts are relatively small, the medium-term land value
238 forecast is more strongly associated with corresponding corn and soybean price forecasts. In
239 addition, our results reveal much stronger correlation between these two forecasts for crop
240 reporting districts with more intensive crop production and thus heavier reliance on crop income
241 as a source for farm income. Finally, the preferences of agricultural professionals are stable over
242 time, with more optimistic professionals forecasting higher values for both short- and medium-
243 term forecasts than their peers.

244 This paper has important practical implications for farm management and land investment and
245 appraisals. First, our results show that experts' opinion surveys land price expectations are
246 somewhat rational in the sense that their movements are positively correlated with fluctuations in
247 crop market fundamentals. Secondly, the medium-term expectation is more closely tied with
248 market fundamentals while short-term expectation is often in response to a host of instantaneous
249 factors that may not drive long-run land market movements. Finally, expected land prices for a
250 local area are governed by factors that influence the net income in that area most, and factors

251 other than crop prices, such as livestock market trends and recreation demand, are critical for
252 land market trends in non-crop-intensive areas.

253 Although this paper uses data from agricultural professionals based in Iowa, the results and
254 implications are relevant for other Corn Belt states. We recognize that more work is needed to
255 further examine the cross-market correlation between crop and land price forecasts, in particular
256 a formal model to link crop prices and margins to land values over time. Currently, we are also
257 examining the accuracy of the crop and land price forecasts through comparison with the realized
258 future values, and investigating how agricultural professionals form these short-term and long-
259 term land price expectations.
